# STA 437/2005: Methods for Multivariate Data Week 9: Non-linear Dimension Reduction Techniques

Piotr Zwiernik

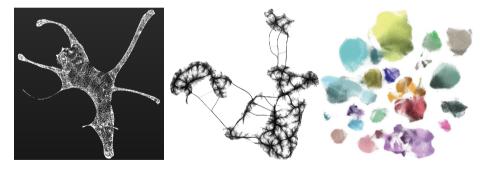

University of Toronto

## Why Principal Component Analysis may not be enough?

PCA struggles with non-linear relationships.

High-dimensional datasets often lie on low-dimensional manifolds.

Linear projections may destroy these geometric information.

We will now discuss four popular non-linear dimensionality reduction techniques: multi-dimensional scaling, spectral embedding, and UMAP.

# Multi-dimensional Scaling (MDS)

- ► In its classical version this is essentially PCA.
- MDS allows us to introduce some fundamental concepts.

## Problem Setup

Consider *n* objects and a measure  $\delta_{ij} \ge 0$  of their dissimilarity (small if similar);  $\delta_{ii} = 0$ . Define  $\Delta = (\delta_{ij}) \in \mathbb{R}^{n \times n}$ :  $\delta_{ii} = 0$  for all  $i, \delta_{ij} \ge 0$  for all  $i \ne j$ .

In classical MDS: there exist  $\mathbf{x}_1, \ldots, \mathbf{x}_n \in \mathbb{R}^m$  such that  $\delta_{ij} = \|\mathbf{x}_i - \mathbf{x}_j\|$ .

In general, there need not be a Euclidean distance defining this metric.

#### Multidimensional Scaling

Find a configuration of points  $\mathbf{y}_1, \ldots, \mathbf{y}_n$  in  $\mathbb{R}^d$  ( $d \ll n$ ) such that:

 $\|\mathbf{y}_i - \mathbf{y}_j\| \approx \delta_{ij}.$ 

The solution for classical MDS is particularly simple.

# Classical MDS: $\delta_{ij} = \|\mathbf{x}_i - \mathbf{x}_j\|$

If 
$$\delta_{ij} = \|\mathbf{x}_i - \mathbf{x}_j\|$$
, we have:  

$$\delta_{ij}^2 = (\mathbf{x}_i - \mathbf{x}_j)^\top (\mathbf{x}_i - \mathbf{x}_j) = (\mathbf{X}\mathbf{X}^\top)_{i,i} + (\mathbf{X}\mathbf{X}^\top)_{j,j} - 2(\mathbf{X}\mathbf{X}^\top)_{i,j}$$

The Hadamard product  $\Delta \odot \Delta = [\delta_{ij}^2]$  can be written as:

$$\Delta \odot \Delta = \operatorname{diag}(\boldsymbol{X}\boldsymbol{X}^{\top})\boldsymbol{1}\boldsymbol{1}^{\top} + \boldsymbol{1}\boldsymbol{1}^{\top}\operatorname{diag}(\boldsymbol{X}\boldsymbol{X}^{\top}) - 2\boldsymbol{X}\boldsymbol{X}^{\top}$$

Reintroducing the centering matrix  $H = I_n - \frac{1}{n} \mathbf{1} \mathbf{1}^{\top}$ , we obtain

$$B := -\frac{1}{2}H(\Delta \odot \Delta)H = H\mathbf{X}(H\mathbf{X})^{\top} = \tilde{\mathbf{X}}\tilde{\mathbf{X}}^{\top}.$$

This matrix contains all inner products  $\tilde{\mathbf{x}}_i^{\top} \tilde{\mathbf{x}}_j$  for  $1 \leq i, j \leq n$ .

Let  $\mathbf{Y} \in \mathbb{R}^{n imes d}$  be the matrix with projected data  $\mathbf{y}_1, \dots, \mathbf{y}_n \in \mathbb{R}^d$ .

We want to make sure  $B = \tilde{\mathbf{X}} \tilde{\mathbf{X}}^\top \approx \mathbf{Y} \mathbf{Y}^\top =: \mathbf{M}$ 

- ▶ In this way  $\|\mathbf{y}_i \mathbf{y}_j\| \approx \|\mathbf{x}_i \mathbf{x}_j\|$  as desired.
- One way to assure this is to minimize  $\sum_{i,j} (\tilde{\mathbf{x}}_i^\top \tilde{\mathbf{x}}_j \mathbf{y}_i^\top \mathbf{y}_j)^2 = \|B M\|_F^2$ .

• The Frobenius norm 
$$||A||_F = \sqrt{\sum_{i,j} A_{ij}^2}$$
.

Note that  $rank(M) \leq d$  but otherwise  $M \in \mathbb{R}^{n \times n}$  is arbitrary.

**Optimization problem:** Minimize  $||B - M||_F^2$  subject to rank $(M) \le d$ .

**Optimization problem:** Minimize  $||B - M||_F^2$  subject to rank $(M) \le d$ .

Let  $B = V \Lambda V^{\top}$  be the spectral decomposition with  $\operatorname{diag}(\Lambda)$  non-increasing.

Eckart-Young Theorem

The optimal M satisfies  $\widehat{M} = V_d \Lambda_d V_d^{\top}$ , where

▶ 
$$\Lambda_d = \operatorname{diag}(\lambda_1, \ldots, \lambda_d)$$
 has *d* largest eigenvalues of *B*.

•  $V_d \in \mathbb{R}^{n \times d}$  contains the first *d* columns of *V*.

We then take  $\mathbf{Y} = V_d \Lambda_d^{1/2}$ , which gives us our low-dimensional embedding.

We next show that this is the same answer we would get using PCA!

Both methods rely on the singular value decomposition (SVD) of  $\tilde{\mathbf{X}} = H\mathbf{X} = VDU^{\top}$ .

Here is the key insight:

▶ PCA: Finds principal components from the eigenvectors of X̃<sup>T</sup>X = U(D<sup>T</sup>D)U<sup>T</sup>.
 ▶ MDS: Finds embeddings from the eigenvectors of X̃X<sup>T</sup> = V(DD<sup>T</sup>)V<sup>T</sup>.

The columns of U are the principal directions and the scores  $\mathbf{y}_1, \ldots, \mathbf{y}_n$  are taken as the first d columns of  $\tilde{\mathbf{X}} U = VD$ .

As a result,  $\mathbf{y}_1, \ldots, \mathbf{y}_n$  are precisely the points obtained by classical MDS.

# Spectral Embedding (aka Laplacian Eigenmaps)

#### Main ideas

Data:  $\mathbf{x}_1, \ldots, \mathbf{x}_n \in \mathbb{R}^m$ . Find low dimensional representation  $\mathbf{y}_1, \ldots, \mathbf{y}_n \in \mathbb{R}^d$ .

#### Links to manifold learning

We look for a truly nonlinear method that is able to learn the underlying manifold.

The main idea is to keep track of local geometry:

• The embedding of  $\mathbf{x}_i$  should depend mostly on points close to  $\mathbf{x}_i$ .

How to keep track of the local geometry in the data?

Construct a weighted graph G = (V, E, W):

- Vertices  $V = \{1, 2, ..., n\}$  (data points).
- Edges *E* based on proximity (e.g., *k*-nearest neighbors or  $\epsilon$ -neighborhood).
- Weights  $W_{ij}$  measure similarity, e.g.  $W_{ij} = 1$  or  $W_{ij} = \exp(-\|\mathbf{x}_i \mathbf{x}_j\|^2/2\sigma^2)$ .

If  $ij \notin E$  we always set  $W_{ij} = 0$ , also  $W_{ii} = 0$  for all i = 1, ..., n.

#### Graph Laplacian

Graph Laplacian is the main object encoding the "geometry of the data".

The Laplacian matrix  $L \in \mathbb{S}^n$  encodes the structure of the graph:

• Degree matrix D (diagonal): 
$$D_{ii} = \sum_{j} W_{ij}$$
,  $i = 1, ..., n$ .

- ▶ Graph Laplacian: L = D W, where W is the weight matrix  $W = (W_{ij})$ .
- Normalized Laplacian:  $L_{\rm N} = D^{-1/2}LD^{-1/2}$ .

**Important exercise:** Show  $\mathbf{x}^{\top} L \mathbf{x} = \frac{1}{2} \sum_{i,j} W_{ij} (x_i - x_j)^2$  for all  $\mathbf{x} \in \mathbb{R}^n$ .

Properties of *L*:

- ► *L* is positive semi-definite.
- $\blacktriangleright$  L1 = 0, that is, smallest eigenvalue is zero with eigenvector 1.
- If G is connected  $\operatorname{rank}(L) = n 1$ .

Fix *d*. The embedding  $\mathbf{y}_1, \ldots, \mathbf{y}_n \in \mathbb{R}^d$  is obtained by minimizing:

$$rac{1}{2}\sum_{i=1}^n\sum_{j=1}^n W_{ij}\|\mathbf{y}_i-\mathbf{y}_j\|^2$$

#### Key insight

High  $W_{ij}$  enforces small  $\|\mathbf{y}_i - \mathbf{y}_j\|$ .

Note: This is still not well defined because  $\mathbf{y}_1 = \ldots = \mathbf{y}_n = \mathbf{0}$  is a solution so we need to refine this idea a bit.

Let  $\mathbf{Y} \in \mathbb{R}^{n \times d}$  be the embedded data matrix. Recall L = D - W and  $L\mathbf{1} = \mathbf{0}$ . Proposition We have:  $\frac{1}{2} \sum_{i,j} W_{ij} \|\mathbf{y}_i - \mathbf{y}_j\|^2 = \operatorname{tr}(\mathbf{Y}^\top L \mathbf{Y}) = \operatorname{tr}(\mathbf{Y}^\top D \mathbf{Y}) - \operatorname{tr}(\mathbf{Y}^\top W \mathbf{Y})$ Proof: As for MDS we can show that the matrix  $E = [\|\mathbf{y}_i\|_{1 \to 1}^2 + \operatorname{tr}(\mathbf{y}^\top W \mathbf{Y})$ 

Proof: As for MDS we can show that the matrix  $E = [||\mathbf{y}_i - \mathbf{y}_j||^2]_{i,j}$  takes the form

$$E = \operatorname{diag}(\mathbf{Y}\mathbf{Y}^{\top})\mathbf{1}\mathbf{1}^{\top} + \mathbf{1}\mathbf{1}^{\top}\operatorname{diag}(\mathbf{Y}\mathbf{Y}^{\top}) - 2\mathbf{Y}\mathbf{Y}^{\top}$$

and so  $\frac{1}{2} \sum_{i,j} W_{ij} \|\mathbf{y}_i - \mathbf{y}_j\|^2 = \frac{1}{2} \operatorname{trace}(WE)$ .

*D* is diagonal and *E* has zeros on the diagonal and so  $\frac{1}{2}$ trace(*WE*) =  $-\frac{1}{2}$ trace(*LE*). Since  $L\mathbf{1} = \mathbf{0}$  we get also that  $-\frac{1}{2}$ trace(*LE*) = trace(*L***YY**<sup> $\top$ </sup>).

#### Introducing constraints to the optimization problem

#### Constraint 1 (Fixing scale)

To avoid trivial solutions it is convenient to assume  $\mathbf{Y}^{\top} D \mathbf{Y} = I_d$ .

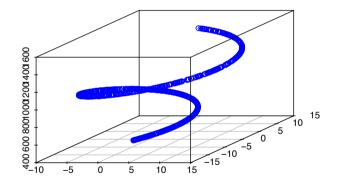

Defining 
$$\tilde{\mathbf{Y}} = D^{1/2}\mathbf{Y}$$
 we get  $\tilde{\mathbf{Y}}^{\top}\tilde{\mathbf{Y}} = I_d$  (orthonormal columns  $\tilde{\mathbf{y}}_1, \dots, \tilde{\mathbf{y}}_d$ ).  
Now trace $(\mathbf{Y}^{\top}L\mathbf{Y}) = \text{trace}(\tilde{\mathbf{Y}}^{\top}L_N\tilde{\mathbf{Y}}) = \sum_{i=1}^d \tilde{\mathbf{y}}_i^{\top}L_N\tilde{\mathbf{y}}_i$ .

From PCA: the optimum given by eigenvectors of  $L_N$  for smallest eigenvalues. Note that  $L_N D^{1/2} \mathbf{1} = D^{-1/2} L \mathbf{1} = \mathbf{0}$  so  $\tilde{\mathbf{y}}_0 := D^{1/2} \mathbf{1}$  is a zero-eigenvector.

Constraint 2:  $\tilde{\mathbf{y}}_0 \perp \tilde{\mathbf{y}}_i$  for  $i = 1, \dots, n$ In addition we assume  $\tilde{\mathbf{Y}}^\top D^{1/2} \mathbf{1} = \mathbf{Y}^\top D \mathbf{1} = \mathbf{0}$ 

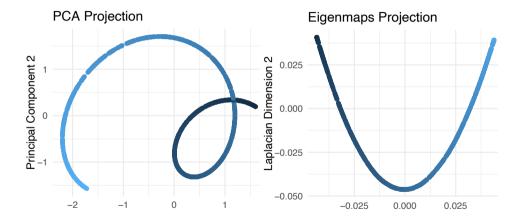

Spectral embedding: minimize trace( $\mathbf{Y}^{\top} L \mathbf{Y}$ ) subject to  $\mathbf{Y}^{\top} D \mathbf{Y} = I_d$  and  $\mathbf{Y}^{\top} D \mathbf{1} = \mathbf{0}$ 

Consider datapoints lying on the twisted curve as on the picture below:

We now represent these data in 2D comparing PCA and Laplacian Eigenmaps.

- **PCA**: Projects data linearly, collapsing structure.
- ► Laplacian Eigenmaps: Preserves local geometry, unfolding the manifold.

Note that PCA joins points that are far from each other in the original dataset.

# Uniform Manifold Approximation and Projection (UMAP)

- ► This is a popular, state-of-the-art method.
- ▶ It relies on various choices that are not fully theoretically justified.
- ► We provide a high level overview.

UMAP is a nonlinear dimensionality reduction technique that improves on eigenmaps.

#### Advantages over PCA, MDS, and Eigenmaps:

- Has manifold learning abilities.
- Balances local and global structure.
- Scales efficiently to large datasets.
- More robust to parameter choices.

UMAP is a state-of-the-art data visualization and pattern discovery tool.

The key idea is similar to the spectral embedding.

- 1. Construct k-Nearest Neighbor (kNN) Graph.
- 2. Initialize Embedding using Laplacian Eigenmaps.
- 3. **Optimize** embedding via stochastic gradient descent (SGD).

UMAP uses a different loss function than Laplacian Eigenmaps, which makes it, in principle, more robust to parameter choices.

Construct k-Nearest Neighbors (kNN) graph; e.g. with k = 15.

Define "probabilities" of i, j being connected based on neighbor distances:

$$p_{j|i} = \exp\left(-\frac{\|\mathbf{x}_i - \mathbf{x}_j\| - \rho_i}{\sigma_i}
ight),$$

where  $\rho_i = \min_{k \neq i} \|\mathbf{x}_i - \mathbf{x}_k\|$  and  $\sigma_i$  is a scaling factor.

Symmetrize probabilities:

$$p_{ij} = p_{j|i} + p_{i|j} - p_{j|i}p_{i|j}.$$

Note that the closest neighbor gets always connected with pr. 1.

▶ This about  $p_{ii}$  as edge weights.

## Step 2 and 3: Data Graph in the Embedding Space and matching

Compute pairwise similarities in low-dimensional space:

$$q_{ij} = \frac{1}{1 + a \|\mathbf{y}_i - \mathbf{y}_j\|^{2b}},\tag{1}$$

where, by default,  $a \approx 1.929$ ,  $b \approx 0.7915$ .

The matching between the original and the embedded space is probability-inspired.

Cost Function (Fuzzy Cross-Entropy)

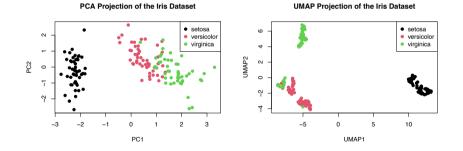

$$c(\mathbf{y}_1,\ldots,\mathbf{y}_n) = \sum_{i
eq j} \left( p_{ij}\lograc{p_{ij}}{q_{ij}} + (1-p_{ij})\lograc{1-p_{ij}}{1-q_{ij}} 
ight).$$

Here c depends on  $\mathbf{y}_1, \ldots, \mathbf{y}_n$  through  $q_{ij}$ 's defined in (1).

- Attractive and repulsive forces to balance local and global structure.
- Uses block-coordinate descent to minimize cost.

#### Example: Iris Dataset

- Comparison of PCA and UMAP on Iris dataset.
- PCA struggles to separate classes clearly.
- ▶ UMAP better preserves local and global structures.

Note: Given a new data point UMAP has to be recalculated from scratch!
